

# Database Systems (資料庫系統)

November 25, 2009

Lecture #9

1

## Announcement

- TA will talk about midterm exam and grading guide.

2

# Hash-Based Indexing

## Chapter 11

3

## Introduction

- Hash-based indexes are best for equality selections. Cannot support range searches.
  - Equality selections are useful for natural join operations.

4

## Review: Tree Index

- ISAM vs. B+ trees.
  - What is the main difference between them?
    - Static vs. dynamic structure
  - What is the tradeoff between them?
    - Graceful table growth/shrink vs. concurrency performance

5

## Similar tradeoff for hashing

- Possible to exploit tradeoff between dynamic structure for better performance?
- Static hashing technique
- Two dynamic hashing techniques
  - Extendible Hashing
  - Linear Hashing

6

## Basic Static Hashing

- # primary pages fixed, allocated sequentially, never de-allocated; overflow pages if needed.
- $h(k) \bmod N =$  bucket to which data entry with key  $k$  belongs. ( $N =$  # of buckets)
  - $N = 2^i$  (or the bucket number is the  $i$ -least significant bits)

7

## Static Hashing (Contd.)

- Buckets contain data entries.
- Hash function takes search key field of record  $r$  and distribute values over range  $0 \dots N-1$ .
  - $h(\text{key}) = (a * \text{key} + b)$  usually works well.
  - $a$  and  $b$  are constants; lots known about how to tune  $h$ .
- Cost for insertion/delete/search:
  - 2/2/1 disk page I/Os (no overflow chains).

8

## What is the performance problem for static hashing?

- Long overflow chains can develop and degrade performance.
  - Why poor performance? Scan through overflow chains linearly.
- How to fix this problem?
  - Extendible and Linear Hashing: Dynamic techniques to fix this problem.

9

## Extendible Hashing

- Simple Solution – remove overflow chain.
- When bucket (primary page) becomes full, ..
  - Re-organize file by adding (doubling) buckets.
- What is the cost concern in doubling buckets?
  - High cost: rehash all entries - reading and writing all pages is expensive!

10

## How to minimize the rehashing cost?

- Use another level of indirection
  - Directory of pointers to buckets
- Insert 0 (00)
  - Double the directory (no rehashing)
  - Split just the overflow bucket.
- What is cost here?

11

## Extendible Hashing

- Directory much smaller than file, so doubling much cheaper. Only one page of data entries is split.
- How to adjust the hash function?
  - Before doubling directory
    - $h(r) \rightarrow 0..N-1$  buckets.
  - After doubling directory?
    - $h(r) \rightarrow 0..2N-1$  (the range is doubled)

12

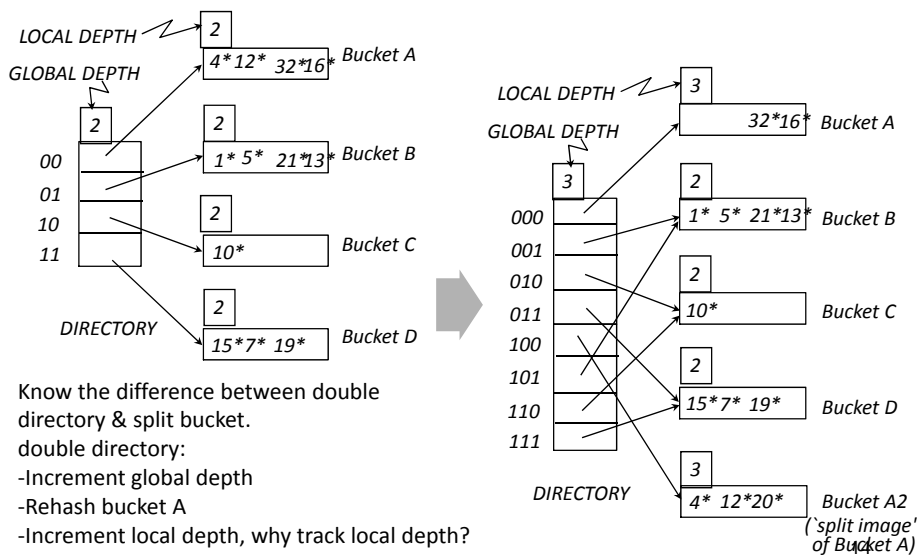

# Example

- Directory is array of size 4.
- What info this hash data structure maintains?
  - Need to know current #bits used in the hash function
    - Global Depth
  - May need to know #bits used to hash a specific bucket
    - Local Depth
  - Can global depth < local depth?

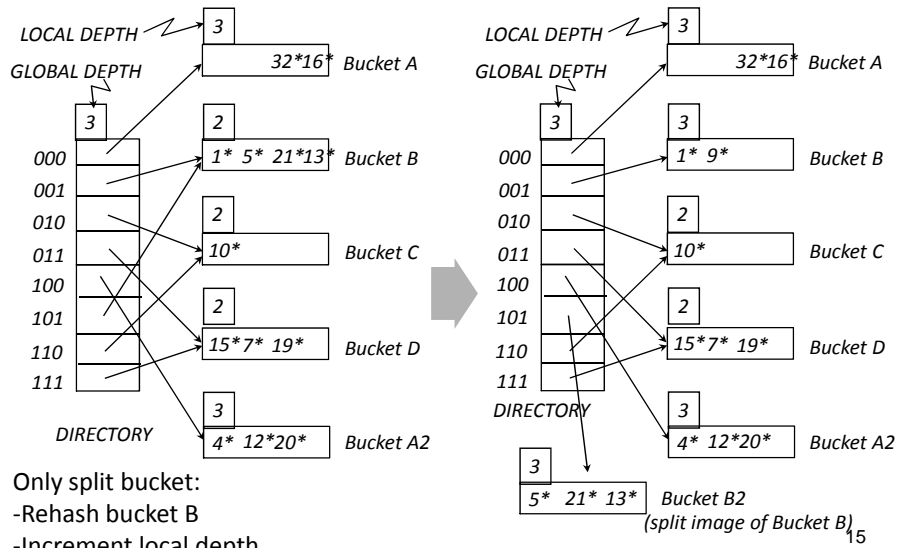

13

## Insert 20 (10100): Double Directory

- Know the difference between double directory & split bucket.
- double directory:
- Increment global depth
  - Rehash bucket A
  - Increment local depth, why track local depth?

## Insert 9 (1001): only Split Bucket

## Points to Note

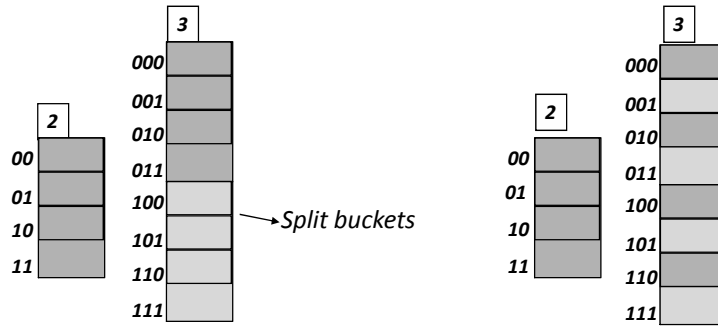

- What is the global depth of directory?
  - Max # of bits needed to tell which bucket an entry belongs to.
- What is the local depth of a bucket?
  - # of bits used to determine if an entry belongs to this bucket.
- When does bucket split cause directory doubling?
  - Before insert, bucket is full & local depth = global depth.
- How to efficiently double the directory?
  - Directory is doubled by copying it over and 'fixing' pointer to split image page.
  - Note that you can do this only by using the least significant bits in the directory.

# Directory Doubling

Why use least significant bits in directory?

⇔ Allows for doubling via copying!

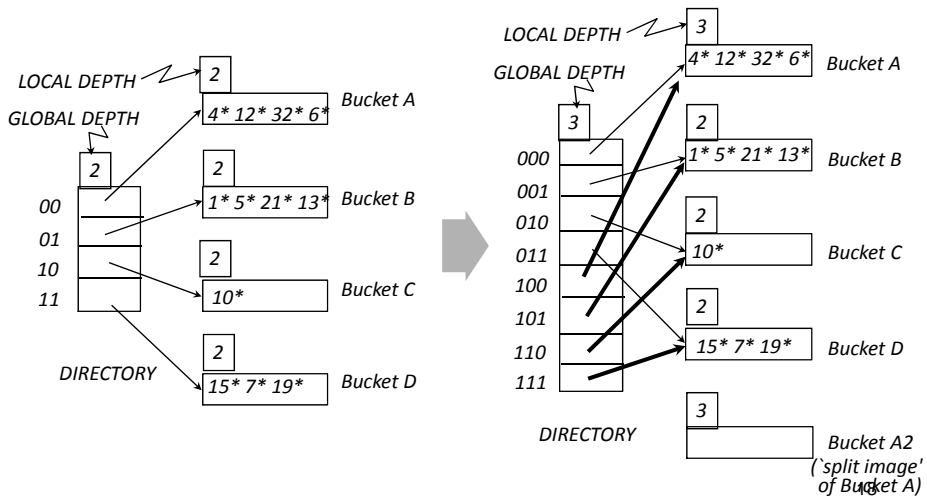

Least Significant

vs.

Most Significant

17

# Directory Copying via Insertion 20 (10100)

## Comments on Extendible Hashing

- If directory fits in memory, equality search answered with one disk access; else two.
- What is the problem with extendible hashing?
  - Consider if the distribution of hash values is skewed (concentrates on a few buckets)
  - Directory can grow large.
- Can you come up with one insertion leading to multiple splits?

19

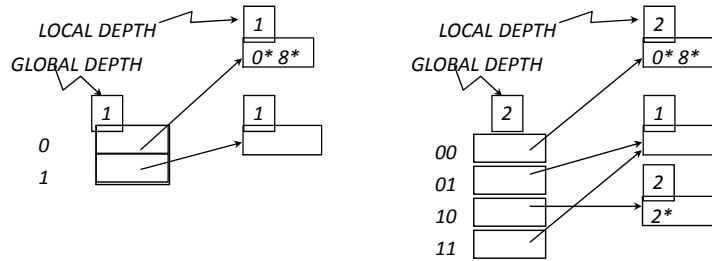

## Skewed data distribution (multiple splits)

- Assume each bucket holds two data entries
- Insert 2 (binary 10) – how many times of DIR doubling?
- Insert 16 (binary 10000) – how many times of DIR doubling?
- How to solve this data skew problem?

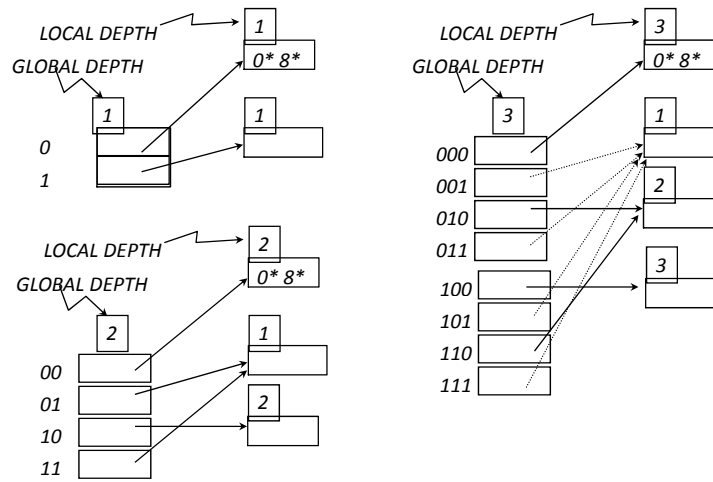

20

## Insert 2 (10)

21

## Insert 16 (10000)

22

## Comments on Extendible Hashing

- Delete: If removal of data entry makes bucket empty, can be merged with 'split image'. If each directory element points to same bucket as its split image, can halve directory.

23

## Delete 10\*

24

## Delete 15\*, 7\*, 19\*

25

## Linear Hashing (LH)

- Another dynamic hashing scheme, as an alternative to Extendible Hashing.
- What are problems in static/extendible hashing?
  - Static hashing: long overflow chains
  - Extendible hashing: data skew causing large directory
- Is it possible to come up with a more balanced solution?
  - Shorter overflow chains than static hashing
  - No need for directory in extendible hashing
    - How do you get rid of directory (indirection)?

26

## Linear Hashing (LH)

- Basic Idea:
  - Pages are split when overflows occur – but not necessarily the page with the overflow.
  - Splitting occurs in turn, in a round robin fashion.
    - one by one from the first bucket to the last bucket.
- Use a family of hash functions  $h_0, h_1, h_2, \dots$ 
  - Each function's range is twice that of its predecessor.
  - When all the pages at one level (the current hash function) have been split, a new level is applied.
  - Splitting occurs gradually
  - Primary pages are allocated in order & consecutively.

27

## Linear Hashing Verbal Algorithm

- Initial Stage.
  - The initial level distributes entries into  $N_0$  buckets.
  - Call the hash function to perform this  $h_0$ .

28

## Linear Hashing Verbal Algorithm

- Splitting buckets.
  - If a bucket overflows its primary page is chained to an overflow page (same as in static hashing).
  - Also when a bucket overflows, some bucket is split.
    - The first bucket to be split is the first bucket in the file (*not* necessarily the bucket that overflows).
    - The next bucket to be split is the second bucket in the file ... and so on until the  $N$ th. has been split.
    - When buckets are split their entries (including those in overflow pages) are distributed using  $h_1$ .
  - To access split buckets the next level hash function ( $h_1$ ) is applied.
  - $h_1$  maps entries to  $2N_0$  (or  $N_1$ ) buckets.

29

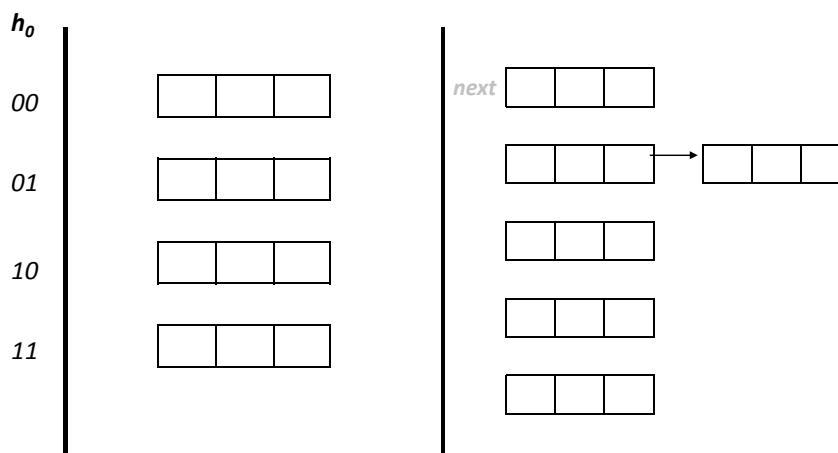

## Linear Hashing Example

- Initially, the index level equal to 0 and  $N_0$  equals 4 (three entries fit on a page).
- $h_0$  range = 4 buckets
- Note that **next** indicates which bucket is to split next. (Round Robin)
- Now consider what happens when 9 (1001) is inserted (which will not fit in the second bucket).

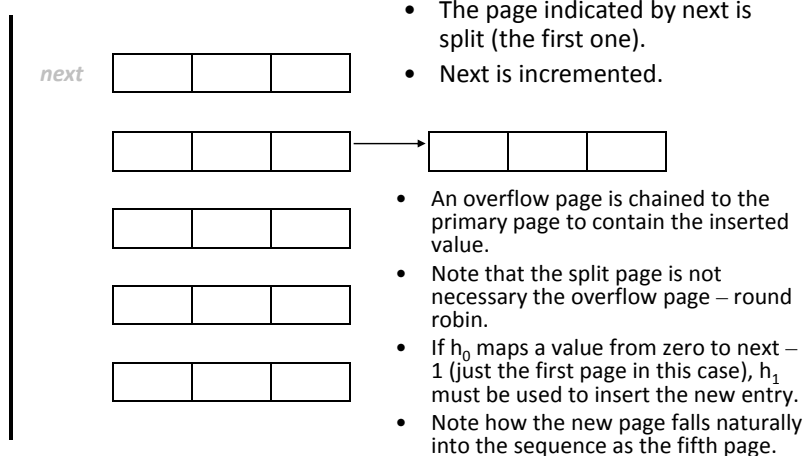

30

## Insert 9 (1001)

31

## Linear Hashing Example 2

- The page indicated by next is split (the first one).
- Next is incremented.
- An overflow page is chained to the primary page to contain the inserted value.
- Note that the split page is not necessary the overflow page – round robin.
- If  $h_0$  maps a value from zero to next – 1 (just the first page in this case),  $h_1$  must be used to insert the new entry.
- Note how the new page falls naturally into the sequence as the fifth page.

32

Insert 8 (1000), 7(111), 18(10010), 14(1100)

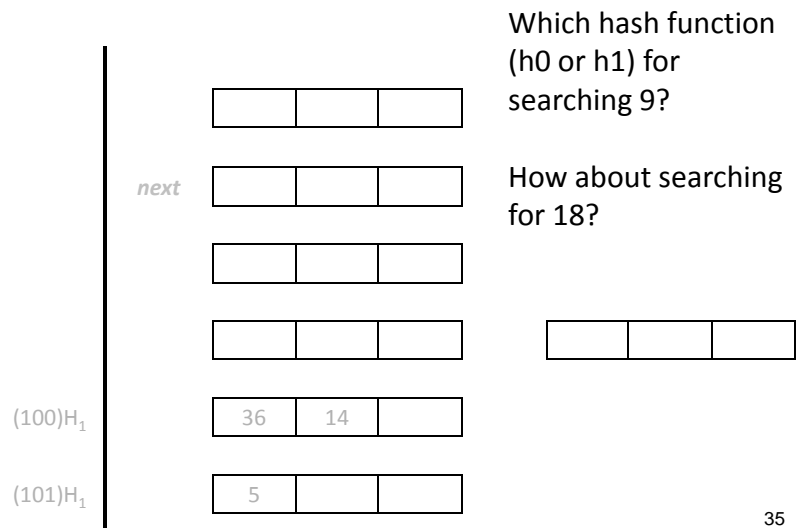

33

Before Insert 11 (1011)

34

## After Insert 11 (1011)

## Linear Hashing

- Insert 32, 16<sub>2</sub>
- Insert 10, 13, 23<sub>3</sub>
- After the 2<sup>nd</sup>. split the base level is 1 ( $N_1 = 8$ ), use  $h_1$ .
- Subsequent splits will use  $h_2$  for inserts between the first bucket and *next-1*.

$h_1$	$h_1$
$h_1$	$h_1$
$h_1$	-
-	-

## Notes for Linear Hashing

- Why linear hashing does not need a directory but extendible hashing needs one?
  - Consider finding  $i$ -th bucket
  - New buckets are created in order (sequentially, i.e., round robin) in linear hashing
- Level progression:
  - Once all  $N_i$  buckets of the current level ( $i$ ) are split the hash function  $h_i$  is replaced by  $h_{i+1}$ .
  - The splitting process starts again at the first bucket and  $h_{i+2}$  is applied to find entries in split buckets.

37

## LH Described as a Variant of EH

- Can you describe linear hashing using extendible hashing (EH)?
  - Begin with an EH index where directory has  $N$  elements.
  - Use overflow pages, split buckets round-robin.
  - First split is at bucket 0. (Imagine directory being doubled at this point.) But elements  $\langle 1, N+1 \rangle$ ,  $\langle 2, N+2 \rangle$ , ... are the same. So, need only create directory element  $N$ , which differs from 0, now.
    - When bucket 1 splits, create directory element  $N+1$ , etc.
- So, directory can double gradually. Also, primary bucket pages are created in order. If they are *allocated* in sequence too (so that finding  $i$ 'th is easy), we actually don't need a directory! Voila, LH.

38

39

## The New World is Flat

- With computer and network, the playing field is being leveled across the world.
- There is no end to what can be done by whom
  - Before: manufacturing products (Made in Taiwan, Made in China)
  - Now: anything including service industry
- This is called outsourcing
- The rule of Capitalist economy:
  - Work goes to the place where it can be done cheapest and most efficient

40

## Outsourcing Examples

- Customer services moving to call centers in India
  - Credit cards, banks, insurance, Microsoft, ...
- Radiologists in India and Australia
- E-tutoring
- Jetblue & homesourcing
- Tax preparation outsourcing
- MacDonald Flatfries and burgers
- Kenichi Ohmae (大前研一)

41

## Outsourcing and ME in Taiwan?

- So anyone on this planet may be replaced by anyone on this planet for cheaper and more efficiency
  - Yes, for any jobs – high/low tech, manufacturing/service
  - Scaring? Consider massive amount of smart & cheap labors in China and India
- Oops ... this is happening NOW here in Taiwan!
  
- So one can compete or collaborate globally with anyone on this planet -> opportunity.

42
